How do we overcome gravity ks2

This easy science experiment is a fun way to demonstrate the concept of gravity to young children. You'll just need a few supplies, including paperclips and magnets, to take part in this cool science activity! This activity correlates with NGSS: Disciplinary Core Idea PS2.B. Follow our Science for Kids Pinterest board! Here's a fun way for young children to explore gravity. Kids will first observe how gravity is always pulling objects toward the Earth by using paperclips and string. Then the super cool part- children will use magnets to explore how gravity can easily be overcome by other forces- almost like defying gravity! (This post contains affiliate links.) See it in Action! Whenever I invite my kids to participate in science activities, my main goal is NOT for them to master a set concept, but simply to allow them to explore the activity in their own way. Giving this freedom to children inspires them to make predictions and critically think about the world around them in a pressure-free setting. What exactly is gravity? Gravity is a force that tries to pull two objects toward each other. Earth's gravity is what keeps you on the ground, what causes objects to fall, and is why the objects fall down rather than up! Materials for Gravity Experiment Important: Not only are small magnets choking hazards, but magnet ingestions pose a serious threat to the health of children. NEVER leave any child unattended with magnets. Never allow any child under 3 to use magnets. Directions for Gravity Experiment 1. Start by tying some paperclips to pieces of string. Then tie the string onto a small dowel rod or stick. 2. Lift up the dowel rod so the paperclips hang from the string. Which direction do the paperclips point? What happens if you tilt the stick? Theo was amazed to observe that no matter which way he tilted the stick or how steep an angle he tilted the stick, the paperclips always pointed right down at the ground! We talked about how the Earth's gravity is what holds us and other things to the ground. The paperclips are being pulled toward the Earth by gravity, but they can't fall because the string is holding them in the air. No matter which way we tilted the dowel rod, the paperclips were still being pulled straight toward the Earth by gravity. Next we explored how gravity can easily be overcome by other forces using magnets. 3. Place three magnets along a metal ruler. (If you're using a wooden ruler, you can tape the magnets to the top.) 4. Suspend the ruler from two stacks of blocks, books, or other materials. Be sure the magnets are facing down. 5. Take the paper clips and string off your dowel rod. 6. Take one paperclip and hold it until it's just suspended below the first magnet. Tape the string in place onto the table (or whatever surface your activity is on). Do this with the other two paperclips. 7. After taping the strings in place below the magnets, remove the ruler and observe what happens. All the paperclips fall to the ground! We talked about why the paperclips were not going up into the air after we removed the magnets. 8. Put the ruler with magnets back above the paperclips. Slowly lift each paperclip toward each magnet until they are all suspended. The kids were very excited about this demonstration! We talked about how the magnetic force between the paperclip and magnet were stronger than the pull of the Earth's gravity on the paperclip, so the paperclip was able to remain in the air rather than fall back to the ground. Lucy and I came up with other forces that seemed to defy gravity- like static electricity holding strands of hair straight up in the air or how the hot air in a hot-air balloon can lift people off the ground. Want to go even further? Even more activities about gravity to inspire creativity and critical thinking for various ages. All activities on Buggy and Buddy are activities I feel are safe for my own children. Contact your child's pediatrician for guidance if you are not sure about the safety/age appropriateness of an activity. Never leave your child unattended. The author and blog disclaim liability for any damage, mishap, or injury that may occur from engaging in any of these activities on this blog. Gravity is the force by which a planet or other body draws objects toward its center. The force of gravity keeps all of the planets in orbit around the sun. What else does gravity do? Why do you land on the ground when you jump up instead of floating off into space? Why do things fall down when you throw them or drop them? The answer is gravity: an invisible force that pulls objects toward each other. Earth's gravity is what keeps you on the ground and what makes things fall. An animation of gravity at work. Albert Einstein described gravity as a curve in space that wraps around an object—such as a star or a planet. If another object is nearby, it is pulled into the curve. Image credit: NASA Anything that has mass also has gravity. Objects with more mass have more gravity. Gravity also gets weaker with distance. So, the closer objects are to each other, the stronger their gravitational pull is. Earth's gravity comes from all its mass. All its mass makes a combined gravitational pull on all the mass in your body. That's what gives you weight. And if you were on a planet with less mass than Earth, you would weigh less than you do here. Image credit: NASA You exert the same gravitational force on Earth that it does on you. But because Earth is so much more massive than you, your force doesn't really have an effect on our planet. Gravity in our universe Gravity is what holds the planets in orbit around the sun and what keeps the moon in orbit around Earth. The gravitational pull of the moon pulls the seas towards it, causing the ocean tides. Gravity creates stars and planets by pulling together the material from which they are made. Gravity not only pulls on mass but also on light. Albert Einstein discovered this principle. If you shine a flashlight upwards, the light will grow imperceptibly redder as gravity pulls it. You can't see the change with your eyes, but scientists can measure it. Black holes pack so much mass into such a small volume that their gravity is strong enough to keep anything, even light, from escaping. Gravity on Earth Gravity is very important to us. We could not live on Earth without it. The sun's gravity keeps Earth in orbit around it, keeping us at a comfortable distance to enjoy the sun's light and warmth. It holds down our atmosphere and the air we need to breathe. Gravity is what holds our world together. However, gravity isn't the same everywhere on Earth. Gravity is slightly stronger over places with more mass underground than over places with less mass. NASA uses two spacecraft to measure these variations in Earth's gravity. These spacecraft are part of the Gravity Recovery and Climate Experiment (GRACE) mission. The GRACE mission helps scientists to create maps of gravity variations on Earth. Areas in blue have slightly weaker gravity and areas in red have slightly stronger gravity. Image credit: NASA/University of Texas Center for Space Research GRACE detects tiny changes in gravity over time. These changes have revealed important details about our planet. For example, GRACE monitors changes in sea level and can detect changes in Earth's crust brought on by earthquakes. Loading... Gravity attracts all objects towards each other. Gravity has been around since the very beginning of the universe, and it works the same way everywhere in the universe, on all kinds of different objects, of all different sizes (larger than atoms – those are held together by atomic forces instead).How much gravity an object has depends on how big it is (or to be specific, how much mass it has). It also depends on how close you are to the object; the closer you are, the stronger the gravity.Gravity is very important to our everyday lives. Without Earth's gravity we would fly right off our planet! We'd all have to be strapped down all the time and if you kicked a ball, it would fly off forever. While it might be fun to try for a few minutes, we certainly couldn't live life on Earth without gravity.Gravity also is important on a larger scale. It is the Sun's gravity that keeps the Earth in orbit around the Sun. Life on Earth needs the Sun's light and warmth to survive. Gravity helps the Earth to stay just the right distance from the Sun, so it's not too hot or too cold.Nobody fully understands how gravity works, or even why gravity exists. One way of looking at gravity is to think of it not as a force like magnetism, but instead as a natural result of the way mass bends space. Any object with mass (like a star) pushes on space and bends it, so that other objects (like planets) that are moving in a straight line are also going around the star. It looks to us like the star is pulling on the planet, but really the star is bending space.The bigger the object's mass, the more gravity it will have; the smaller the mass of the object, the less gravity it is subject to.Gravity guides the growth of plants and other vegetation.Black holes have the strongest gravitational pull in the entire universe.The Earth is a giant magnet. Its magnetic field is like a bar magnet at its centre.Sir Isaac Newton discovered gravity about 300 years ago. The story is that Newton saw an apple fall out of a tree. When this happened he realised there was a force that made it occur, and he called it gravity.Ocean tides are caused by the gravity of the moon.If you could travel from planet to planet your mass would stay the same, but your weight would vary depending on how the gravity of that planet pulled on you. Mars is smaller and has less mass than Earth and as a result it has less gravity. If you weigh 100 pounds on Earth, you would weigh 38 pounds on Mars.At some point when falling, the friction from the air will equal the force of gravity and the object will be at a constant speed. This is called the terminal velocity. For a sky diver this speed is around 100 miles per hour!We don't actually "feel" gravity. We only feel the effects of trying to overcome it by jumping or when we fall.Gravity always pulls, it never pushes.You are shrinking right now. Every day you are taller in the morning than you are at night. In fact, at the end of each day you are about 1/2 inch (1.25 centimetres) shorter than when you got up that morning. If you don't believe it, have someone measure you when you get up in the morning and then again before you go to bed. This isn't because your heavy backpack has weighed you down. It happens because of gravity. As you walk around during the day, gravity is pulling you down, or more correctly, toward the centre of Earth. Lying down to sleep at night gives your spine a chance to stretch back to your full height.On Earth, gravity isn't entirely even. Because the globe isn't a perfect sphere, its mass is distributed unevenly, which means slightly uneven gravity.One mysterious gravitational anomaly is in the Hudson Bay of Canada. This area has lower gravity than other regions, and a 2007 study found that now-melted glaciers were to blame. The ice that once covered the area during the last Ice Age has long since melted, but the Earth hasn't entirely snapped back from the burden. Since gravity over an area is proportional to the mass on top of that region, and the glacier's imprint pushed aside some of the Earth's mass, gravity is a bit less strong in the ice sheet's imprint. The slight deformation of the crust explains the unusually low gravity in the area. In some places, it's almost half as strong as it is elsewhere!Black holes are some of the most destructive objects in the universe, named because nothing, not even light, can escape their gravitational clutches. At the centre of our galaxy is a massive black hole with the mass of 3 million suns. The black hole isn't really a danger to us Earthlings – it's both far away and it's remarkably calm.In the very beginning of the universe, after the Big Bang, gravity pulled atoms together to make stars and planets. Once the stars and planets had formed, gravity kept the planets in orbit around the stars, and moons orbiting around the planets. And on each planet that is large enough, gravity keeps an atmosphere around the planet.On Earth, gravity keeps the air around us (and everything else) from drifting off into space. Gravity also causes hot air to rise while colder air falls (which in turn causes wind).Astronauts dealing with a lack of gravity!As skydivers fall to Earth the force pulling them down is gravity.Gravity holds the moon in orbit around EarthAll objects fall at the same rate – air resistance affects this speed.Items with a different mass fall at the same rate in a vacuum.It is said that Sir Isaac Newton wrote his theory about gravity after watching an apple fall to the ground.A portrait of Sir Isaac Newton. Gravity or gravitational forces are forces of attraction. It's like the Earth pulling on you and keeping you on the ground. That pull is gravity at work.Every object in the universe that has mass exerts a gravitational pull, or force, on every other mass. The size of the pull depends on the masses of the objects. You exert a gravitational force on the people around you, but that force isn't very strong, since people aren't very big. When you look at really large masses, like the Earth and Moon, the gravitational pull becomes very impressive. The gravitational force between the Earth and the molecules of gas in the atmosphere is strong enough to hold the atmosphere close to our surface. Smaller planets, that have less mass, may not be able to hold an atmosphere.A larger size does not mean a bigger mass. Imagine two balls that are about the same size, like a football and a bowling ball. Will they have the same mass? No.An easy way to think about mass is to consider how much matter or "stuff" you can find inside the object. The amount of matter in the object will affect how heavy it is, meaning gravity has plenty of matter to 'grab onto'. In the case of the football, air molecules make up most of its inside. The outside of the ball looks solid, but cut it in half and the ball will look like an empty shell. Whereas the inside of a bowling ball is usually completely solid, so if you cut it in half you will end up with two solid pieces. The bowling ball has more matter inside it, making it denser than the football. Therefore, its mass will be greater than the soccer ball's mass.Mass is measured in grams (g) or kilograms (kg) but is NOT a force. The weight of an object is the force caused by gravity pulling down on the mass of an object. It is measured in newtons (N). Weight is measured using a force meter. The bigger the weight attached to the force meter, the more the spring inside the force meter stretches.The Earth always produces the same acceleration on every object. If you drop an acorn or a piano, they will gain velocity (speed) at the same rate. Although the gravitational force the Earth exerts on the objects is different, their masses are just as different, so the effect we observe (acceleration) is the same for each. The Earth's gravitational force accelerates objects when they fall. It constantly pulls, and the objects constantly speed up. You might be thinking, "What about feathers? They fall so slowly." Obviously, there is air all around us. When a feather falls, it falls slowly because the air is in its way. There is a lot of air resistance and that resistance makes the feather move more slowly. The forces at work are the same. If you dropped a feather in a container with no air (a vacuum), it would drop as fast as a baseball.Isaac Newton was an incredibly clever man. He was a scientist and a mathematician. In 1687, Newton published a book about mathematics which is thought to be one of the important books in the history of science. In it he describes universal gravitation and the three laws of motion, concepts that remained at the forefront of science for centuries after. Newton was known to have said that his work on formulating a theory of gravitation was inspired by watching an apple fall from a tree and wondering about what made it fall downwards.Words to know:Universe - all matter and energy that exists in the vastness of space, whether known to human beings or notGravity - the attraction due to gravitation that the Earth or another astronomical object exerts on an object on or near its surfaceAtoms - the smallest portion into which an element can be dividedMass - an object has mass (say 100 kg).This makes it heavy enough to weigh 100 kgOrbit - the path that an astronomical object such as a planet, moon, or satellite follows around a larger astronomical object such as the SunMagnetism - the phenomenon of physical attraction for iron, found in magnets or made by a moving electric charge or currentFriction - the rubbing of two objects against each other when one or both are movingAnomaly - something strange and difficult to identify or classifyDeformation - the act or process of damaging, disfiguring, or spoiling the look of something, or the condition of being damaged, disfigured, or spoiledDenser - closer together, more tightly-packedNewtons - The correct unit for measuring force is the Newton, which is abbreviated N.Force meter - Force meters contain a spring connected to a metal hook. The spring stretches when a force is applied to the hook. The bigger the force applied, the longer the spring stretches and the bigger the reading.Velocity - the speed at which something moves or happensConcepts - ideas or principlesRelated VideosJust for fun...Best kids' books about gravity Find out more about gravity:See for yourselfTry some practical science experiments: understand more about gravity and explain what you know or try one of TheSchoolRun's at-home science experiments (Experiments and science fun for KS1 and KS2, a subscriber resource).Watch Expedition 16 flight engineer Dan Tani discuss and demonstrate gravity and Newton's laws from the International Space Station on the NASA websiteAlso see
